

1. Take a list, reverse it completely using slicing, and then swap its new first and last elements.
2. Given `a = [10, 90, 70, 50, 60, 20]`, find and print the 2nd largest item.
3. Given `a = [1, 2, 3, 5, 6, 7, 8, 9]` and `b = [1, 3, 5, 7, 9]`, return a new list containing only the elements that are unique across both lists (items present in one list but not both).
4. Given the list `[5, 10, 15, 20]`, remove the item at index 2 and add it to the very end of the list.
5. Given `store1 = {'apple': 5, 'banana': 3}` and `store2 = {'orange': 4, 'banana': 10}`, merge them into a single dictionary where `store2` overwrites duplicate keys from `store1`.
6. Given the tuple `nums = (1, 5, 3, 5, 2, 5, 4)`, find exactly how many times 5 appears and the index at which it first appears.
7. Given the tuple `fruits = ("apple", "banana", "orange", "berries")`, unpack the first item into a variable named `start`, the last item into a variable named `end`, and ignore the middle two items.
